Implement Client Script &UI Policy (Incident)

Requirement Analysis Phase:

Requirement Identification

The first step in the Requirement Analysis Phase is to identify the requirements of the Incident Management system. The Incident form is analyzed to understand the problems faced by users while creating and updating incidents. The required fields, field behavior, validation needs, and conditions are identified. This helps to define how the Client Script and UI Policy should work in the Incident form.

Incident Form Requirements

The Incident form contains important fields such as Caller, Category, Subcategory, Impact, Urgency, Priority, Short Description, Description, Assignment Group, and Assigned To. Each field has a specific purpose in Incident Management. The requirements are analyzed to identify which fields should be mandatory, visible, or read-only based on specific conditions. This helps users enter the required information correctly.

Client Script Requirements

Client Script is required to perform actions based on user interaction with the Incident form. It can be used to validate the information entered by the user, display messages, set field values, and perform dynamic actions. The required conditions and expected behavior are identified during this phase before creating the Client Script. This helps reduce incorrect data entry and improves the accuracy of Incident information.

UI Policy Requirements

UI Policy is required to control the behavior of fields in the Incident form without using complex scripting. Based on specific conditions, UI Policy can make fields Mandatory, Visible, or Read-only. For example, when a particular value is selected, another field can automatically become mandatory or visible. This makes the Incident form easier to use and ensures that important information is provided.

Expected Outcome

The Requirement Analysis Phase provides a clear understanding of the requirements needed to implement Client Script and UI Policy. The expected outcome is a user-friendly Incident form with proper field validation, visibility, mandatory conditions, and read-only controls. This helps reduce data entry errors, improve data accuracy, and make the Incident Management process more efficient
