Implement Client Script & UI Policy (Incident)

Project Development Phase

Introduction:

The Project Development Phase is the stage where the planned requirements and designs are converted into a working application. In this project, Client Script and UI Policy are implemented in the Incident module to improve the user interface and automate form behaviour.

Client Script:

A Client Script is a JavaScript code that runs on the client side of the ServiceNow application. It is used to control the behaviour of fields in an Incident form based on specific conditions.

For example, a Client Script can be used to automatically set a field value, display an alert message, make a field mandatory, or change a field based on the user's input. This helps to reduce manual work and improves the accuracy of incident records.

UI Policy:

A UI Policy is used to dynamically change the behaviour of fields on an Incident form without requiring complex coding. It can make fields mandatory, visible, or read-only based on a particular condition.

Implementation in Incident Module:

The Client Script and UI Policy are implemented in the Incident module according to the project requirements. The Client Script handles the required client-side actions, while the UI Policy controls the visibility, mandatory status, and read-only behaviour of the fields.

Testing:

After implementation, the Client Script and UI Policy are tested with different Incident conditions. The form behaviour is checked to ensure that the fields are displayed, hidden, made mandatory, or made read-only correctly.
