Implement Client Script & UI Policy (Incident)

Project Testing Phase:

Client Script Testing

The Client Script is tested under different conditions in the Incident form. It is checked whether the field values are updated correctly, alert messages are displayed properly, and the required fields are updated according to the user's input.

UI Policy Testing

The UI Policy is tested to verify the visibility, mandatory, and read-only conditions of fields in the Incident form. It is checked whether the fields become visible or hidden based on specific conditions, whether the field values are displayed correctly, and whether read-only fields cannot be modified by the user.

Test Case Verification

Different test cases are performed for both Client Script and UI Policy. The actual output is compared with the expected output. If any error or incorrect behaviour is found, it is identified and corrected.

Functional Testing

The Incident form is tested with different inputs and conditions to ensure that all implemented functionalities work properly. The form behaviour is verified after applying the Client Script and UI Policy.

Test Cases

Different test cases are created and executed for the Client Script and UI Policy. In each test case, appropriate input is provided and the actual result is compared with the expected result. If any error occurs, it is identified and corrected.

Result

After testing, the Client Script and UI Policy are confirmed to work correctly according to the specified conditions. The fields in the Incident form function properly as visible, hidden, mandatory, or read-only based on the requirements.
